June 13, 2008

Abstract

We introduce the concepts of complex Grassmannian codes and designs. Let $\mathcal{G}_{m,n}$ denote the set of m -dimensional subspaces of $\mathbb{C}^n$: then a *code* is a finite subset of $\mathcal{G}_{m,n}$ in which few distances occur, while a *design* is a finite subset of $\mathcal{G}_{m,n}$ that polynomially approximates the entire set. Using Delsarte's linear programming techniques, we find upper bounds for the size of a code and lower bounds for the size of a design, and we show that association schemes can occur when the bounds are tight. These results are motivated by the bounds for real subspaces recently found by Bachoc, Coulangéon and Nebe, and the bounds generalize those of Delsarte, Goethals and Seidel for codes and designs on the complex unit sphere.

1 Introduction

In this paper, we introduce the concept of complex Grassmannian codes and designs: codes and designs in the collection of fixed-rank subspaces of a complex vector space.

In the 1970's, Delsarte [10] developed a series of excellent bounds for certain error-correcting codes by treating codewords as points in an association scheme and then applying linear programming. Shortly thereafter, Delsarte, Goethals and Seidel [11] showed that the same technique could also be used on systems of points on the real or complex unit sphere, which they called spherical codes

*email:aroy@qis.ucalgary.ca

and spherical designs; this resulted in important contributions to problems in sphere-packing [9, Chapter 9]. This linear programming technique, which is now known as “Delsarte LP theory”, has proved surprisingly portable. Recently, Bachoc, Coulangéon and Nebe [3] generalized the results of Delsarte, Goethals and Seidel to real Grassmannian spaces, and Bachoc [2] pointed out that “the same game” can be played over the complex numbers. In this paper, we investigate more closely the case of complex Grassmannian codes.

The motivation for studying complex Grassmannians comes from the theory of quantum measurements. Roughly speaking, any complex Grassmannian 1-design defines a projective measurement in the theory of quantum mechanics. It has recently been discovered that complex projective 2-designs correspond to quantum measurements that are optimal for the purposes of nonadaptive quantum state tomography [21]. In fact, this is also true in the more general Grassmannian setting: complex Grassmannian 2-designs are the optimal choices of measurements for nonadaptive quantum state tomography when the observer only has access to measurements with a restricted number of outcomes. More details will appear in a paper by Godsil, Rötteler, and the author [13]. Complex Grassmannians also play a role in certain wireless communication protocols [1].

Define $\mathcal{G}_{m,n}$ to be the set of m -dimensional subspaces of an n -dimensional complex vector space. Without loss of generality, we will always assume $m \leq n/2$. Usually, we will represent a subspace a by its $n \times n$ projection matrix P_a . The inner product on $\mathcal{G}_{m,n}$ is the trace inner product for projection matrices:

$$\begin{aligned}\langle a, b \rangle &:= \text{tr}(P_a^* P_b) \\ &= \text{tr}(P_a P_b).\end{aligned}$$

Since $\langle a, b \rangle = \langle b, a \rangle$, the inner product is real. This is a measure of separation, or distance, between two subspaces—note that is not a distance metric per se: the inner product of P_a with itself is maximal rather than minimal. However, the *chordal distance* [8], defined by

$$d_c(P_a, P_b) := \sqrt{m - \text{tr}(P_a P_b)},$$

is a monotonic function of the inner product. Given a finite set of inner product values $\mathcal{A}$, an $\mathcal{A}$ -code is a subset S of $\mathcal{G}_{m,n}$ such that

$$\mathcal{A} = \{\text{tr}(P_a P_b) : a, b \in S, a \neq b\}.$$

An s -distance set is an $\mathcal{A}$ -code with $|\mathcal{A}| = s$. This generalizes the concept of an s -distance set on the complex unit sphere: if u and v are unit vectors, then

their separation distance on the unit sphere is a function of

$$|u^*v|^2 = \text{tr}(uu^*vv^*).$$

We are interested in codes of maximal size for a fixed $\mathcal{A}$ or s , and bounds on their size based on zonal polynomials. Table 1 in Section 6 gives a summary of the bounds for small $|\mathcal{A}|$.

The outline of this paper is as follows. In Section 2, we describe the orbits of pairs of subspaces in $\mathcal{G}_{m,n}$ under the action of $U(n)$: these orbits play a significant role in the bounds derived later on. In Sections 3, 4 and 5, we develop the necessary representation theory background needed for our LP bounds. In particular, we discuss the decomposition of the square-integrable functions on $\mathcal{G}_{m,n}$ into irreducible representations of $U(d)$, and the zonal polynomials for these representations. The results in this section are all known, and the development is quite similar to that of Bachoc, Coulanges and Nebe for real Grassmannians. In fact, the complex case is actually easier than the real case, because representations of the unitary group $U(n)$ are easier to describe than representations of the orthogonal group $O(n)$. In Section 6, we develop absolute and relative bounds for codes, and show how these bounds for $\mathcal{G}_{m,n}$ reduce to known bounds for complex spherical codes when $m = 1$. These bounds are compared to some other known bounds for subspaces in Section 7. In Section 9, we consider Grassmannian designs. Grassmannian codes enjoy a form of duality with complex Grassmannian designs, very similar to real Grassmannian codes or spherical codes. In Section 8, we give examples in which the bounds are tight. In many cases codes of maximal size or designs of minimal size have the structure of an association scheme, which we describe in Section 10.

2 Orbitals

In this section we describe the orbits of pairs of elements of $\mathcal{G}_{m,n}$ under the action of $U(n)$.

First, we claim that $\mathcal{G}_{m,n}$ can be identified with a factor group of the unitary group, $U(n)/(U(m) \times U(n-m))$. For, consider the first m columns of a matrix of $U(n)$ as the basis for a subspace a of dimension m in $\mathbb{C}^n$, letting the last $n-m$ columns be a basis for $a^\perp$. Then a is invariant under the action of $U(m)$ on the first m columns, while $a^\perp$ is invariant under $U(n-m)$.

As a result of this factor group, $U(n)$ acts on $\mathcal{G}_{m,n}$ as follows: if U is in $U(n)$ and P_a is the projection matrix for $a \in \mathcal{G}_{m,n}$, then

$$U : P_a \mapsto UP_aU^*.$$

This action is an isometry, in that it preserves the trace inner product on $\mathcal{G}_{m,n}$. Unlike the complex unit sphere, however, $U(n)$ is not 2-homogeneous on $\mathcal{G}_{m,n}$: $U(n)$ does not act transitively on pairs of subspaces with the same distance. In other words, the fact that $\text{tr}(P_a P_b) = \text{tr}(P_c P_d)$ does not imply that there is a unitary matrix mapping a to c and b to d . In order to use zonal polynomials, we need to understand the orbits of pairs in $\mathcal{G}_{m,n}$ under this isometry group, which requires principal angles.

Given a and b in $\mathcal{G}_{m,n}$, the *principal angles* $\theta_1, \dots, \theta_m$ between a and b are defined as follows: firstly, θ_1 is the largest angle that occurs between any two unit vectors $a_1 \in a$ and $b_1 \in b$:

$$\theta_1 := \min_{\substack{a_1 \in a \\ b_1 \in b}} \arccos |a_1^* b_1|.$$

Secondly, θ_2 is the largest angle that occurs between any two unit vectors $a_2 \in a \cap a_1^\perp$ and $b_2 \in b \cap b_1^\perp$. Similarly define $\theta_3, \dots, \theta_m$. These principle angles are closely related to the eigenvalues of $P_a P_b$: the first m eigenvalues of $P_a P_b$ are $\{\cos^2 \theta_1, \dots, \cos^2 \theta_m\}$. Because of this correspondence, for the remainder of this paper we simply refer to the eigenvalues $y_i := \cos^2 \theta_i$ (rather than the values θ_i) as the principal angles between a and b . Note that $n - m$ of the eigenvalues of $P_a P_b$ are zero, so we need only consider the first m eigenvalues. Conway, Hardin, and Sloane [8] accredit the following lemma to Wong [24, Theorem 2].

Lemma 2.1. *The principal angles characterize the orbits of pairs of subspaces under $U(n)$.*

Proof. Suppose $U \in U(n)$ maps projection matrices P_a and P_b to P_c and P_d respectively. Then by similarity, the eigenvalues of

$$P_c P_d = (U P_a U^*)(U P_b U^*) = U P_a P_b U^*$$

are the same as the eigenvalues of $P_a P_b$.

Conversely, we show that if $P_a P_b$ and $P_c P_d$ have the same eigenvalues, then some unitary matrix U maps a to c and b to d . We do this by unitarily mapping a and b into a canonical form that depends only on the eigenvalues of $P_a P_b$.

Let M_a be an $n \times m$ matrix whose columns $[a_1, \dots, a_m]$ are an orthonormal basis for a , so that $M_a M_a^* = P_a$ and $M_a^* M_a = I$. Similarly define $M_b = [b_1, \dots, b_m]$ for b . Suppose $M_a^* M_b$ has singular value decomposition UDV^* , where U and V are $m \times m$ unitary and D is $m \times m$ diagonal. Then $(M_a U)^*(M_b V) = D$. Since the columns of $M_a U$ are another orthonormal basis for a , without loss of generality we replace M_a by $M_a U$ and likewise replace

M_b with $M_b V$. In other words, we may assume without loss of generality that $M_a^* M_b = D$, where D is a diagonal matrix of singular values.

Next, define the columns of $N_a = [a_{m+1}, \dots, a_n]$ to be any orthonormal basis for $a^\perp$, so that $N_a N_a^* = I - P_a$ and $N_a^* N_a = I$. Further assume that $N_a^* M_b = QR$, where Q is $(n-m) \times (n-m)$ unitary and R is $(n-m) \times m$ upper triangular (the QR -decomposition of $N_a^* M_b$). Then $Q^* N_a^* M_b = R$, and the columns of $N_a Q$ form another orthonormal basis for $a^\perp$. Replacing N_a by $N_a Q$, we may assume without loss of generality that $N_a^* M_b$ is upper triangular.

Finally, let $U_a := \begin{pmatrix} M_a^* \\ N_a^* \end{pmatrix}$; this is an $n \times n$ unitary matrix. Then

$$U_a M_a = \begin{pmatrix} I_m \\ 0 \end{pmatrix}; \quad U_a M_b = \begin{pmatrix} D \\ R \end{pmatrix}.$$

If $P_a P_b$ has eigenvalues $\cos^2 \theta_i$, then $M_a^* M_b = D$ has singular values $\cos \theta_i$. Moreover, since $U_a M_b$ has orthonormal columns, it follows that R also has orthogonal columns. We may therefore assume that R is not just the upper triangular but diagonal, with diagonal entries $\sin \theta_i$. Thus U_a is a unitary matrix which maps M_a and M_b into the form

$$M_a \mapsto \begin{pmatrix} I_m \\ 0 \end{pmatrix}, \quad M_b \mapsto \begin{pmatrix} \cos \theta_1 & & & \\ & \ddots & & \\ & & \cos \theta_m & \\ \sin \theta_1 & & & \\ & \ddots & & \\ & & \sin \theta_m & \\ & & & 0 \end{pmatrix}.$$

Since any pair (M_a, M_b) with principal angles $\cos^2 \theta_i$ can be mapped to this canonical form, it follows that the eigenvalues of $P_a P_b$ characterize the orbits of pairs (a, b) under the unitary group. $\square$

3 Representations

In this section and the next, we develop the representation theory needed for Grassmannian LP bounds.

As is standard for compact Lie groups, we work with functions on $\mathcal{G}_{m,n}$ to find irreducible representations. Define an inner product for functions on $\mathcal{G}_{m,n}$

as follows:

$$\langle f, g \rangle := \int_{\mathcal{G}_{m,n}} \overline{f(a)} g(a) da.$$

Here da is the unique measure invariant on $\mathcal{G}_{m,n}$, normalized so that $\int da = 1$. That such a measure exists and is unique (the Haar measure) follows from the fact that $\mathcal{G}_{m,n}$ is a compact Lie group. Equivalently, we may write

$$\langle f, g \rangle := \int_{U(n)} \overline{f(U^* P_a U)} g(U^* P_a U) dU,$$

where dU is the Haar measure on $U(n)$, and P_a is the projection matrix for some fixed $a \in \mathcal{G}_{m,n}$. Now let $L^2(\mathcal{G}_{m,n})$ denote the space of square-integrable functions on $\mathcal{G}_{m,n}$. Then $U(n)$ acts on $f \in \mathcal{G}_{m,n}$ as follows:

$$(Uf)(P_a) := f(U^* P_a U).$$

It follows that $L^2(\mathcal{G}_{m,n})$ provides a representation of $U(n)$. As we will see, this representation can be decomposed into irreducible subrepresentations explicitly, and the decomposition is *multiplicity-free*: no irreducible representation of $U(n)$ occurs more than once in $L^2(\mathcal{G}_{m,n})$.

Since $U(n)$ is a compact Lie group, its irreducible representations are well-studied: see for example [22, 15, 6, 12]. Every irreducible representation is indexed by a *dominant weight* [22, Theorem 7.34]. In the case of $U(n)$, we may take these weights to have the form [6, Theorem 38.3]

$$\lambda = (\lambda_1, \dots, \lambda_n) : \lambda_1 \geq \lambda_2 \geq \dots \geq \lambda_n, \lambda_i \in \mathbb{Z}.$$

The dimension of the irreducible representation V_λ indexed by λ is given by *Weyl's character formula* [22, Theorem 7.32]. In the case of $U(n)$, the formula reduces to:

$$\dim V_\lambda = \prod_{1 \leq i < j \leq n} \frac{\lambda_i - \lambda_j + j - i}{j - i}. \quad (3.1)$$

For example, the standard representation of $U(n)$ is indexed by $\lambda = (1, 0, \dots, 0)$, which gives

$$\dim V_{(1,0,\dots,0)} = n.$$

Note that there is more than one irreducible representation with the same dimension.

Each dominant weight may also be thought of as a form acting on a maximal Abelian subgroup of the Lie group. Here λ acts on the diagonal matrix $d =$

$\text{diag}(d_1, \dots, d_n) \in U(n)$ as follows:

$$d^\lambda := \prod_{i=1}^n d_i^{\lambda_i}.$$

The next section describes exactly which of these forms contribute to the decomposition of $L^2(\mathcal{G}_{m,n})$.

4 Symmetric spaces

The group $U(n)/U(m) \times U(n-m)$ is an example of a *symmetric space*: a factor group G/K such that G is a connected semisimple Lie group and K is the fixed point set of an involutive automorphism of G . In this section, we use results from Goodman and Wallach [15] to explain how the decomposition of representations of $\mathcal{G}_{m,n}$ follows from this structure.

Let s_m denote the $m \times m$ matrix with backwards diagonal entries of 1 and 0 elsewhere:

$$s_m := \begin{pmatrix} 0 & & 1 \\ & \ddots & \\ 1 & & 0 \end{pmatrix}.$$

Then $U(n, s_n)$ denotes the group of matrices which preserve the Hermitian form $(x, y) \mapsto x^* s_n y$: that is, $U(n, s_n)$ is the set of matrices M such that $M^* s_n M = s_n$. This group is isomorphic to the standard unitary group $U(n)$. Define

$$J_{m,n} := \begin{pmatrix} & & s_m \\ & I_{n-2m} & \\ s_m & & \end{pmatrix},$$

and consider the involution $\theta(M) := J_{m,n} M J_{m,n}$ on $GL_n(\mathbb{C})$. The fixed points of θ have the form

$$M = \begin{pmatrix} a & b & c \\ d & e & d s_m \\ s_m c s_m & s_m b & s_m a s_m \end{pmatrix},$$

so the fixed point set in $GL_n(\mathbb{C})$ is isomorphic to $GL_m(\mathbb{C}) \times GL_{n-m}(\mathbb{C})$.

Lemma 4.1. *The fixed point set K of θ in $G = U(n, s_n)$ is isomorphic to $U(m) \times U(n-m)$. Therefore $\mathcal{G}_{m,n}$ is a symmetric space.*

Proof. For $a = (a_1, \dots, a_m)$, let $\check{a}$ denote the reversal of a , namely

$$\check{a} := s_m a = (a_m, \dots, a_1).$$

If a , b , and c have length m , $n - 2m$ and m respectively, then we have $J_{m,n}(a, b, c)^T = (\check{c}, b, \check{a})^T$. Therefore the 1 and -1 eigenspaces of $J_{m,n}$ are $V_+ = \{(a, b, \check{a})\}$ and $V_- = \{(a, 0, -\check{a})\}$ respectively. These spaces are orthogonal with respect to the form $(x, y) \mapsto x^* s_n y$.

Now K is the set of points in $U(n, s_n)$ which commute with $J_{m,n}$. So decomposing $\mathbb{C}^n$ into $V_+ \oplus V_-$, we have that K is the set of points in $U(n, s_n)$ which leave both V_+ and V_- invariant. In other words, K is the set of points which preserve the form s_n on the subspaces V_+ and V_- . Thus

$$K \cong U(V_+, s_n|_{V_+}) \times U(V_-, s_n|_{V_-}) \cong U(n - m) \times U(m). \quad \square$$

The fact that K is the fixed point set of θ in G implies ([15, Theorem 12.3.5]) that (G, K) is a *spherical pair*: for every irreducible representation V_λ of G , the subspace V_λ^K of points fixed by K satisfies $\dim V_\lambda^K \leq 1$. Those representations such that V_λ^K has dimension exactly 1 are called *spherical representations*. The following theorem [16, Theorem V.4.3] explains how those representation relate to $L^2(G/K)$.

Theorem 4.2. *Let G be a compact simply connected semisimple Lie group, and let $K \leq G$ be the fixed point group of an involutive automorphism of G . Further let $\hat{G}_K$ denote the set of equivalence classes of spherical representations V_λ of G with respect to K . Then $L^2(G/K)$ is a multiplicity-free representation of G , and*

$$L^2(G/K) \cong \bigoplus_{\lambda \in \hat{G}_K} V_\lambda.$$

To describe which representations are spherical, we now consider diagonal subgroups of G and K . For $d = (d_1, \dots, d_n)$, let $\text{diag}(d)$ denote the diagonal matrix with diagonal entries $d_1, \dots, d_n$. Firstly, note that $\text{diag}(d)$ is in $U(n, s_n)$ if and only if $d_{n+1-k} = 1/\bar{d}_k$, where $\bar{d}_k$ is the complex conjugate of d_k . In other words, if $\bar{d}^{-1}$ denotes the vector $(1/\bar{d}_1, \dots, 1/\bar{d}_n)$, then $\text{diag}(d)$ is in $U(n, s_n)$ if and only if $\check{d} = \bar{d}^{-1}$. Secondly, note that if $d = \text{diag}(a, b, c)$ with a and c of length m , then $\theta(d) = (\check{c}, b, \check{a})$. It follows that the diagonal group

$$T := \{\text{diag}(a_1, \dots, a_m, c_{m+1}, \dots, c_{n-m}, a_m, \dots, a_1) : |a_i| = 1, \check{c} = \bar{c}^{-1}\}$$

is contained in K . In fact, it is a maximal Abelian subgroup of K : this is called a *torus* of K .

Recall that the irreducible representations of G are indexed by the dominant weights $\lambda = (\lambda_1, \dots, \lambda_n)$, where $\lambda_i \geq \lambda_{i+1}$ and $\lambda_i \in \mathbb{Z}$. Now the spherical representations of G with respect to K are indexed by those particular dominant

weights such that $t^\lambda = 1$ for all $t = (t_1, \dots, t_n)$ in the torus T (see Goodman and Wallach [15, p. 540]). So a dominant weight λ is spherical if it has the form

$$\lambda = (\lambda_1, \dots, \lambda_m, 0, \dots, 0, -\lambda_m, \dots, -\lambda_1)$$

with $\lambda_1 \geq \dots \geq \lambda_m \geq 0$ and $\lambda_i \in \mathbb{Z}$. In other words:

Theorem 4.3. *The irreducible representations of $U(n)$ occurring in $L^2(\mathcal{G}_{m,n})$ are in one-to-one correspondence with the integer partitions with at most m parts.*

For any partition μ , we let $H_\mu(n)$, or simply H_μ , denote the irreducible representation in $L^2(\mathcal{G}_{m,n})$ isomorphic to $V_{(\mu, 0, \dots, 0, -\check{\mu})}$. The Weyl character formula (equation (3.1)) now tells us the dimension of each H_μ . The first few dimensions are:

$$\begin{aligned} \dim H_{(0)} &= \dim V_{(0, \dots, 0)} = 1 \\ \dim H_{(1)} &= \dim V_{(1, 0, \dots, 0, -1)} = n^2 - 1 \\ \dim H_{(2)} &= \frac{n^2(n-1)(n+3)}{4} \\ \dim H_{(1,1)} &= \frac{n^2(n+1)(n-3)}{4} \\ \dim H_{(2,1)} &= \frac{(n^2-1)^2(n^2-9)}{9} \\ \dim H_{(k)} &= \binom{n+k-2}{k}^2 \frac{n+2k-1}{n-1} \\ \dim H_{(\underbrace{1, \dots, 1}_k)} &= \binom{n+1}{k}^2 \frac{n-2k+1}{n+1} \end{aligned}$$

If $m = 1$, then $\mathcal{G}_{m,n}$ is the complex projective space $\mathbb{C}P^{n-1}$, and only the spaces $H_{(k)}$ occur. In that case $H_{(k)}$ is isomorphic to the space $\text{Harm}(k, k)$ of harmonic polynomials of homogeneous degree k in both z and $\bar{z}$, where $z = (z_1, \dots, z_n)$ is a point on the unit sphere in $\mathbb{C}^n$. Those harmonic polynomials were used by Delsarte, Goethals, and Seidel in their LP bounds for codes and designs the complex unit sphere [11].

We now record a few more representations of $U(n)$ we will need later. Given an nonincreasing sequence of nonnegative integers $\mu = (\mu_1, \mu_2, \dots)$, we say μ has size k and write $|\mu| = k$ if μ is a partition of k ; that is, $\sum_i \mu_i = k$. We also say μ has length l and write $\text{len}(\mu) = l$ if μ has l nonzero entries. For example,

$(2, 1, 0, \dots)$ has size 3 and length 2. Then for fixed $\mathcal{G}_{m,n}$, define $H_k = H_k(m, n)$ as follows:

$$H_k(m, n) := \bigoplus_{\substack{|\mu| \leq k \\ \text{len}(\mu) \leq m}} H_\mu(n).$$

For $k > 0$ this representation is reducible, and H_{k-1} is contained in H_k . When $m = 1$, H_k is isomorphic to the space of homogeneous polynomials degree k in both z and $\bar{z}$ on the unit sphere in $\mathbb{C}^n$. In the next section, we will see that H_k is also the span of the degree- k symmetric polynomials on the principal angles between $a \in \mathcal{G}_{m,n}$ and some fixed $b \in \mathcal{G}_{m,n}$. Moreover, if g and h are polynomials in H_k and $H_{k'}$ respectively, then gh is in $H_{k+k'}$, and in fact $H_{k+k'}$ is spanned by polynomials of that form.

We also let $\text{Hom}_k(n) \subseteq L^2(\mathcal{G}_{m,n})$ denote the space of polynomials which are homogeneous of degree k in the entries of P_a , where P_a is the projection matrix of $a \in \mathcal{G}_{m,n}$. Since the constant function $P_a \mapsto \text{tr}(P_a) = m$ is in $\text{Hom}_1(n)$, it follows that $\text{Hom}_{k-1}(n)$ can be embedded into $\text{Hom}_k(n)$. Similarly for fixed b , the distance function $P_a \mapsto \text{tr}(P_a P_b)$ is in $\text{Hom}_1(n)$. The next section will also show that H_k is a subspace of Hom_k .

James and Constantine [17] further investigated the irreducible subspaces of $L^2(\mathcal{G}_{m,n})$, finding zonal polynomials for each irreducible representation. We describe those results in the next section.

5 Zonal polynomials

A *zonal polynomial* at a point $a \in \mathcal{G}_{m,n}$ is a function on points $b \in \mathcal{G}_{m,n}$ which depends only on the the principle angles between a and b . Given any univariate polynomial $f(x)$ of degree k , we define the *zonal polynomial of f at b* as follows: if $f(x) = \sum_{i=0}^k f_i x^i$, then

$$f_a(b) = \sum_{i=0}^k f_i \text{tr}(P_a P_b)^i.$$

Here P_a and P_b are the projection matrices for a and b . As written, the zonal polynomial is not homogeneous, but by embedding the constant 1 into $\text{Hom}_1(n)$ in the form $\text{tr}(P_b)/m$, the exponents in $f_a(b)$ may be “pushed up” and we may assume f_a is in $\text{Hom}_k(n)$. To see that $f_a(b)$ only depends on the principal angles between a and b , note that $\text{tr}(P_a P_b)$ is simply the sum of the principal angles.

There is another set of zonal polynomials that play a particular role in the theory of Delsarte bounds. Let H_μ be an irreducible representation in $L^2(\mathcal{G}_{m,n})$.

Then for each $a \in \mathcal{G}_{m,n}$, define the *zonal orthogonal polynomial* $Z_{\mu,a}$ to be the unique element of H_μ such that for every $p \in H_\mu$,

$$\langle Z_{\mu,a}, p \rangle = p(a).$$

Then zonal polynomials are invariant under the unitary group, in the following sense:

$$Z_{\mu,b}(a) = \langle U^* Z_{\mu,a}, U^* Z_{\mu,b} \rangle = \langle Z_{\mu,Ua}, Z_{\mu,Ub} \rangle = Z_{\mu,Ub}(Ua).$$

The value of $Z_{\mu,b}(a)$ depends on the $U(n)$ -orbit of (a, b) and therefore depends on the principle angles of a and b . With this in mind we sometimes write $Z_{\mu,a}(b) = Z_\mu(a, b)$ or $Z_{\mu,a}(b) = Z_\mu(y_1, \dots, y_m)$, where $(y_1, \dots, y_m)$ are the principal angles of a and b .

Schur orthogonality [22, Theorem 3.3] for irreducible representations implies that $Z_{\mu,a}$ and $Z_{\nu,b}$ are orthogonal for $\mu \neq \nu$. So, we have

$$\langle Z_{\mu,a}, Z_{\nu,b} \rangle = \delta_{\mu,\nu} Z_\mu(a, b).$$

Moreover, $Z_{\mu,a}(b) = Z_{\mu,b}(a)$ is in fact real and symmetric in a and b . The zonal polynomials satisfy some other important properties, including the following positivity condition:

Lemma 5.1. *For any subset $S \subseteq \mathcal{G}_{m,n}$,*

$$\sum_{a,b \in S} Z_\mu(a, b) \geq 0.$$

Equality holds only when $\sum_{a \in S} Z_{\mu,a} = 0$.

Proof. We have

$$\begin{aligned} \sum_{a,b \in S} Z_\mu(a, b) &= \sum_{a,b \in S} \langle Z_{\mu,a}, Z_{\mu,b} \rangle \\ &= \left\langle \sum_{a \in S} Z_{\mu,a}, \sum_{b \in S} Z_{\mu,b} \right\rangle \\ &\geq 0. \end{aligned}$$

Equality holds if and only if $\sum_{a \in S} Z_{\mu,a} = 0$. □

The second important condition the zonal polynomials satisfy is called the *addition formula*:

Lemma 5.2. *Let $e_1, \dots, e_N$ be an orthonormal basis for the irreducible subspace H_μ . Then*

$$\sum_{i=1}^N \overline{e_i(a)} e_i(b) = Z_\mu(a, b).$$

Proof. Since $Z_{\mu,a}$ is in H_μ , we may write it as a linear combination of $e_1, \dots, e_N$:

$$\begin{aligned} Z_{\mu,a} &= \sum_{i=1}^N \langle e_i, Z_{\mu,a} \rangle e_i \\ &= \sum_i \overline{e_i(a)} e_i. \end{aligned}$$

So, it follows that $Z_{\mu,a}(b) = \sum_i \overline{e_i(a)} e_i(b)$. $\square$

James and Constantine give an explicit formula for the zonal orthogonal polynomials of $\mathcal{G}_{m,n}$ in terms of Schur polynomials, the irreducible characters of $SL(m, \mathbb{C})$. If $y = (y_1, \dots, y_m)$ are variables and $\sigma = (s_1, \dots, s_m)$ is a partition into at most m parts, then the (unnormalized) *Schur polynomial* is defined as

$$X_\sigma(y) := \frac{\det(y_i^{s_j+m-j})_{i,j}}{\det(y_i^{k-j})_{i,j}}.$$

Each Schur polynomial is a symmetric polynomial in $(y_1, \dots, y_m)$. For more information about Schur polynomials, see Stanley [23, Chapter 7]. The *normalized Schur polynomial* X_σ^* is the multiple of X_σ such that $X_\sigma^*(1, \dots, 1) = 1$.

To define the zonal orthogonal polynomials for $\mathcal{G}_{m,n}$, first define the *ascending product*

$$(a)_s := a(a+1) \dots (a+s-1),$$

and given a partition $\sigma = (s_1, \dots, s_m)$, define *complex hypergeometric coefficients*

$$[a]_\sigma := \prod_{i=1}^m (a - i + 1)_{s_i}.$$

Further assume we have a partial order $\leq$ on partitions defined such that $(s_1, \dots, s_m) \leq (k_1, \dots, k_l)$ if and only if $s_i \leq k_i$ for all i . Letting $y + 1 := (y_1 + 1, \dots, y_m + 1)$, the *complex hypergeometric binomial coefficients* $\left[\begin{smallmatrix} \kappa \\ \sigma \end{smallmatrix} \right]$ are given by the formula

$$X_\kappa^*(y + 1) = \sum_{\sigma \leq \kappa} \left[\begin{smallmatrix} \kappa \\ \sigma \end{smallmatrix} \right] X_\sigma^*(y).$$

We can now define the zonal orthogonal polynomials for $\mathcal{G}_{m,n}$. The following result is due to James and Constantine [17].

Theorem 5.3. *Let*

$$\rho_\sigma := \sum_{i=1}^m s_i(s_i - 2i + 1)$$

and let σ and κ partition s and k respectively. Also let

$$[c]_{(\kappa,\sigma)} := \sum_i \frac{\begin{bmatrix} \kappa \\ \sigma_i \end{bmatrix} \begin{bmatrix} \sigma_i \\ \sigma \end{bmatrix}}{(k-s) \begin{bmatrix} \kappa \\ \sigma \end{bmatrix}} \frac{[c]_{(\kappa,\sigma_i)}}{\left(c + \frac{\rho_\kappa - \rho_\sigma}{k-s}\right)},$$

where the summation is over partitions $\sigma_i = (s_1, \dots, s_{i-1}, s_i + 1, s_{i+1}, \dots)$ that are nonincreasing. Then up to normalization, the zonal orthogonal polynomial for H_κ is

$$Z_\kappa(y) := \sum_{\sigma \leq \kappa} \frac{(-1)^s \begin{bmatrix} \kappa \\ \sigma \end{bmatrix} [c]_{(\kappa,\sigma)}}{[a]_\sigma} X_\sigma^*(y),$$

where $y = (y_1, \dots, y_m)$ is the set of principal angles.

The first few normalized Schur polynomials are:

$$\begin{aligned} X_0^*(y) &= 1 \\ X_1^*(y) &= \frac{1}{m} \sum_{i=1}^m y_i \\ X_{1,1}^*(y) &= \frac{1}{\binom{m}{2}} \sum_{i < j} y_i y_j \\ X_2^*(y) &= \frac{1}{\binom{m+1}{2}} \left(\sum_{i=1}^m y_i^2 + \sum_{i < j} y_i y_j \right). \end{aligned}$$

Up to normalization by a constant, the first few zonal orthogonal polynomials are:

$$\begin{aligned} Z_0(y) &= 1 \\ Z_1(y) &= nX_1^*(y) - m \\ Z_{1,1}(y) &= m(m-1) - 2(n-1)(m-1)X_1^*(y) + (n-1)(n-2)X_{1,1}^*(y) \\ Z_2(y) &= m(m+1) - 2(n+1)(m+1)X_1^*(y) + (n+1)(n+2)X_2^*(y). \end{aligned}$$

$\mathcal{A}$	$\{\alpha\}$	$\{\alpha, \beta\}$
Absolute bound	n^2	$\binom{n^2}{2} \quad (m > 1)$
Relative bound	$\frac{n(m - \alpha)}{m^2 - n\alpha}$	$\frac{n(m - \alpha)(m - \beta)}{m^2 \left[\frac{(m+1)^2}{2(n+1)} + \frac{(m-1)^2}{2(n-1)} - (\alpha + \beta) + \frac{n\alpha\beta}{m^2} \right]}$
Relative bound conditions	$\alpha < \frac{m^2}{n}$	$\alpha + \beta \leq \frac{2(m^2n - 4m + n)}{n^2 - 4},$ $\alpha + \beta - \frac{n\alpha\beta}{m^2} < \frac{m^2n - 2m + n}{n^2 - 1}$

Table 1: Upper bounds on $|S|$, when $S \subseteq \mathcal{G}_{m,n}$ is an $\mathcal{A}$ -code.

The correct normalizations satisfy

$$\langle Z_{\mu,a}, Z_{\mu,a} \rangle = Z_{\mu}(1, 1, \dots, 1) = \dim H_{\mu}.$$

With the exception of the case $\mu = 0$ (which is normalized correctly in the formula above), normalizations for Z_{μ} will not play a role in the results which follow.

6 Bounds

Recall that an $\mathcal{A}$ -code is a collection S of subspaces in $\mathcal{G}_{m,n}$ such that $\text{tr}(P_a P_b) \in \mathcal{A}$ for every $a \neq b$ in S . In this section, we find upper bounds on the size of an $\mathcal{A}$ -code in terms of either the cardinality of $\mathcal{A}$ or its elements. A summary of the results for $|\mathcal{A}| \leq 2$ is given in Table 1.

If $\mathcal{A} = \{\alpha_1, \dots, \alpha_k\}$, then the *annihilator* of $\mathcal{A}$ is the function

$$\text{ann}_{\mathcal{A}}(x) := \prod_{i=1}^k (x - \alpha_i),$$

The significance of the annihilator is that $\text{ann}_{\mathcal{A}}(\text{tr}(P_a P_b)) = 0$ for any $a \neq b$ in S . More generally, for any polynomial f , an f -code is a collection S of subspaces such that $f(\text{tr}(P_a)) \neq 0$ and $f(\text{tr}(P_a P_b)) = 0$ for every $a \neq b$ in S . If $\mathcal{A}$ is any set of angles and f is the annihilator of $\mathcal{A}$, then an $\mathcal{A}$ -code is also an f -code.

Theorem 6.1. *If $S \subseteq \mathcal{G}_{m,n}$ is an $\mathcal{A}$ -code, with $|\mathcal{A}| = k$, then*

$$|S| \leq \dim(\text{Hom}_k(n)) \leq \binom{n^2 + k - 1}{k}.$$

Proof. We prove more generally that if S is an f -code, with $\deg(f) = k$, then $|S| \leq \dim(\text{Hom}_k(n))$. The result then follows by taking f to be the annihilator of $\mathcal{A}$.

Consider the zonal polynomials $f_a(b) := f(\text{tr}(P_a P_b))$, for $a \in S$. Note that f_a is in $\text{Hom}_k(n)$, since $f_a(b)$ is a degree- k polynomial in the entries of P_b . Since $f_a(b) = 0$ for every $b \in S$ except a , and $f_a(a) \neq 0$, the set $\{f_a : a \in S\}$ is linearly independent. Thus the number of functions $|S|$ is at most the dimension of the space $\text{Hom}_k(n)$. $\square$

Corollary 6.2. *Let S be a collection of subspaces in $\mathcal{G}_{m,n}$ such that $\text{tr}(P_a P_b) = \alpha$ for all $a \neq b$ in S . Then*

$$|S| \leq n^2.$$

Proof. Use Theorem 6.1 with the degree-1 annihilator of α , which induces zonal polynomials in $\text{Hom}_1(n)$. $\square$

Since $f_a(b)$ is also a degree- k symmetric polynomial in the principal angles of a and b , it follows that f_a is also in $H_k(m, n)$. Then by the same argument as in Theorem 6.1, we have

Corollary 6.3. *If $S \subseteq \mathcal{G}_{m,n}$ is an $\mathcal{A}$ -code, with $|\mathcal{A}| = k$, then*

$$|S| \leq \dim(H_k(m, n)).$$

If equality holds, then the functions f_a form a basis for the space. Moreover, the space $H_k(m, n)$ is exactly the space of functions on S .

Theorem 6.1 and Corollary 6.3 are called *absolute bounds* for Grassmannian codes, because the bounds depend only on the number of different inner product values that occur in S . When $m = 1$ these bounds reduce to the absolute bounds of Delsarte, Goethals and Seidel [11, Theorem 6.1]. There is also a *relative bound*, which depends on the actual values of the inner products and is sometimes tighter.

Theorem 6.4. Let $f(y_1, \dots, y_m) \in \mathbb{R}[y_1, \dots, y_m]$ be a symmetric polynomial such that $f = \sum_{\mu} c_{\mu} Z_{\mu}$, where Z_{μ} is a zonal orthogonal polynomial, and each $c_{\mu} \geq 0$. Further assume that c_0 is strictly positive. If S is a set of subspaces in $\mathcal{G}_{m,n}$ such that $f_a(b) := f(y_1(a, b), \dots, y_m(a, b))$ is nonpositive for every $a \neq b$ in S , then

$$|S| \leq \frac{f(1, \dots, 1)}{c_0}.$$

Proof. Since $f_a(b) \leq 0$ for $b \neq a$, summing over all $b \in S$, we have

$$\sum_{b \in S} f_a(b) \leq f_a(a) = f(1, \dots, 1).$$

Then averaging over all $a \in S$,

$$\begin{aligned} f(1, \dots, 1) &\geq \frac{1}{|S|} \sum_{a, b \in S} f_a(b) \\ &= \frac{1}{|S|} \sum_{\mu} c_{\mu} \sum_{a, b \in S} Z_{\mu}(a, b). \end{aligned}$$

By Lemma 5.1, the inner sum is non-negative for $\mu \neq 0$. If $\mu = 0$, then $Z_0(a, b) = 1$ for all a and b , and hence,

$$\begin{aligned} f(1) &\geq \frac{1}{|S|} c_0 \sum_{a, b \in S} 1 \\ &= c_0 |S|. \end{aligned} \quad \square$$

Equality holds if and only if $f_a(b) = 0$ for every $a \neq b \in S$ and for each $\mu \neq 0$, we have either $c_{\mu} = 0$ or $\sum_{a \in S} Z_{\mu, a} = 0$. (We will see in Section 9 that when $c_{\mu} > 0$ for all $|\mu| \leq \deg(f)$, this implies that we have a Grassmannian t -design.)

By way of example, we consider the case of an $\{\alpha\}$ -code in detail.

Corollary 6.5. Let S be a subset of $\mathcal{G}_{m,n}$ such that $\text{tr}(P_a P_b) = \alpha$ for all $a \neq b$ in S , and $\alpha < m^2/n$. Then

$$|S| \leq \frac{n(m - \alpha)}{m^2 - n\alpha}.$$

Proof. The first two zonal orthogonal polynomials are $Z_0(y) = 1$ and (up to normalization) $Z_1(y) = \sum_{i=1}^m y_i - m^2/n$. The annihilator for α is the polynomial $f(x) = x - \alpha$, which induces the zonal polynomial at subspace a given by

$$f_a(b) = \text{tr}(P_a P_b) - \frac{\alpha \text{tr}(P_b)}{m} = \sum_{i=1}^m y_i - \alpha,$$

for principle angles $y_1, \dots, y_m$ of a and b . Thus we may write

$$\begin{aligned} f(y_1, \dots, y_m) &= \sum_{i=1}^m y_i - \alpha \\ &= c_1 Z_1(y) + \left(\frac{m^2}{n} - \alpha \right) Z_0(y). \end{aligned}$$

Applying Theorem 6.4, we find that

$$|S| \leq \frac{f(1, \dots, 1)}{c_0} = \frac{m - \alpha}{m^2/n - \alpha}. \quad \square$$

When $m = 1$, we recover Delsarte, Goethals and Seidel's bound for complex equiangular lines:

$$|S| \leq \frac{n(1 - \alpha)}{1 - n\alpha}.$$

Similarly, using the zonal orthogonal polynomials $Z_0, Z_1, Z_{1,1}$ and Z_2 , we get a bound on the size of a subset containing two inner products, say α and β .

Corollary 6.6. *Let S be a subset of $\mathcal{G}_{m,n}$ such that $\text{tr}(P_a P_b) \in \alpha, \beta$ for all $a \neq b$ in S . Further assume that*

$$\begin{aligned} \alpha + \beta &\leq \frac{2(m^2 n - 4m + n)}{n^2 - 4}, \\ \alpha + \beta - \frac{n\alpha\beta}{m^2} &< \frac{m^2 n - 2m + n}{n^2 - 1}. \end{aligned}$$

Then

$$|S| \leq \frac{n(m - \alpha)(m - \beta)}{m^2 \left[\frac{(m+1)^2}{2(n+1)} + \frac{(m-1)^2}{2(n-1)} - (\alpha + \beta) + \frac{n\alpha\beta}{m^2} \right]}.$$

When $m = 1$ this reduces to the Delsarte, Goethals and Seidel bound of

$$|S| \leq \frac{n(n+1)(1-\alpha)(1-\beta)}{2 - (n+1)(\alpha + \beta) + n(n+1)\alpha\beta}$$

for lines in complex projective space $\mathbb{C}P^{n-1}$.

7 Other bounds

Certain cases of equality in Corollaries 6.5 and 6.6 also achieve equality for bounds on the size of the largest angle in a set of subspaces. For real Grassmannians, Conway, Hardin and Sloane [8] call these bounds the *simplex* and *orthoplex* bounds. Here we give their complex analogues.

Recall that if P_a be the $n \times n$ projection matrix for $a \in \mathcal{G}_{m,n}$, then P_a is Hermitian with trace m , so $P'_a = P_a - mI/n$ lies in a real space of dimension $n^2 - 1$. Moreover $\|P'_a\|^2 := \text{tr}(P'_a P'_a) = m(1 - m/n)$, so P'_a is embedded onto a sphere of radius $\sqrt{m(1 - m/n)}$ in $\mathbb{R}^{n^2-1}$. Further recall that the chordal distance on $\mathcal{G}_{m,n}$ is defined by

$$\begin{aligned} d_c(a, b)^2 &= m - \text{tr}(P_a P_b) \\ &= \frac{1}{2} \|P_a - P_b\|^2 = \frac{1}{2} \|P'_a - P'_b\|^2. \end{aligned}$$

With this distance, the Grassmannians are isometrically embedded into $\mathbb{R}^{n^2-1}$. The “Rankin bounds” given in Theorem 7.1 below (see [4, Theorems 6.1.1 & 6.1.2]) are bounds on the minimum distance between points on a real sphere as a function of the number of points and the dimension of the space. An *equatorial simplex* refers to a set of N points on the unit sphere that form a simplex in a hyperplane of dimension $N - 1$.

Theorem 7.1. *Given N points on a sphere of radius r in $\mathbb{R}^D$, the minimum distance d between any two points satisfies*

$$d \leq r \sqrt{\frac{2N}{N-1}}.$$

Equality requires $N \leq D+1$ and occurs if and only if the points form a regular equatorial simplex. For $N > D+1$, the minimum distance satisfies

$$d \leq r\sqrt{2},$$

and equality requires $N \leq 2D$. When $N = 2D$, equality occurs if and only if the points are the vertices of a regular orthoplex.

Conway, Hardin and Sloane [8] apply these bounds to get the simplex and orthoplex bounds for real Grassmannians: we can do the same for the complex Grassmannians.

Corollary 7.2. *Given a set S points in $\mathcal{G}_{m,n}$, the largest inner product value $\alpha = \langle a, b \rangle$ between any two points satisfies*

$$\alpha \geq m \frac{m|S| - n}{n|S| - n}. \quad (7.1)$$

Equality requires $|S| \leq n^2$ and occurs if and only if the points form a regular equatorial simplex in $\mathbb{R}^{n^2-1}$. For $|S| > n^2$, the largest inner product β satisfies

$$\beta \geq \frac{m^2}{n}, \quad (7.2)$$

and equality requires $|S| \leq 2(n^2 - 1)$. Equality occurs if the points are the $2(n^2 - 1)$ vertices of a regular orthoplex in $\mathbb{R}^{n^2-1}$.

If S is an $\{\alpha\}$ -code, then solving inequality (7.1) for $|S|$ recovers the relative bound in Corollary 6.5. Moreover, if $|S| = n^2$ (equality in the absolute bound of Corollary 6.2), then

$$\alpha = \frac{m(mn - 1)}{n^2 - 1}.$$

On the other hand, if S is a $\{0, m^2/n\}$ -code, and $m = n/2$, then the relative bound in Corollary 6.6 implies that

$$|S| \leq 2(n^2 - 1),$$

which corresponds to equality in the orthoplex bound (7.2).

8 Examples

In this section we give examples demonstrating the tightness of the bounds in the previous sections.

When the rank m of the Grassmannian subspaces is 1, we recover all the classical results of Delsarte, Goethals and Seidel [11] for lines in complex projective space: their paper gives several examples of bounds with equality. In particular, the upper bound for $\{\alpha\}$ -codes in $\mathbb{C}P^{n-1}$ is n^2 , and equality can only hold with a trace inner product value of $\alpha = 1/(n + 1)$. Examples of tightness have been found for several small values of n and are conjectured to exist for every n . These equiangular lines are sometimes called *symmetric informationally complete POVMs* in the quantum information literature: see [19] for more details or [18] for recent results. Another important example in $\mathcal{G}_{1,n}$ is the relative bound (Corollary 6.6) with inner product values of $\alpha = 0$

and $\beta = 1/n$. The upper bound for the size of an $\{0, 1/n\}$ -code is $n(n+1)$, and when equality is achieved we have what is known as a *maximal set of mutually unbiased bases*. Constructions achieving the bound are known when n is a prime power; see [14] for some constructions and [20] for applications to quantum information.

In the case $m = n/2$, if a is in $\mathcal{G}_{m,n}$, then its orthogonal complement $a^\perp$ is also in $\mathcal{G}_{m,n}$, and a and $a^\perp$ have a trace inner product of 0. Here again, such subspaces have applications in quantum state tomography; more details will be found in [13]. If S is a $\{0, n/4\}$ -code in $\mathcal{G}_{n/2,n}$, then by the relative bound (Corollary 6.6), S has size at most $2(n^2 - 1)$. In these case we may assume that both a and $a^\perp$ are in S , because if a and b have a trace inner product of $n/4$, then so do $a^\perp$ and b . The following construction, due to Martin Rötteler, demonstrates that Corollary 6.6 is tight when n is a power of 2.

Theorem 8.1. *Let $X_1, \dots, X_{n^2-1}$ be the Pauli matrices of order $n = 2^k$, and let*

$$M_i := \frac{1}{2}(I + X_i).$$

Then $\cup_{i=1}^{n^2-1} \{M_i, I - M_i\}$ is the set of projection matrices for a $\{0, n/4\}$ -code of size $2(n^2 - 1)$ in $\mathcal{G}_{n/2,n}$.

More generally, the bound is tight when n is the order of a Hadamard matrix: details of the following construction will appear in [13].

Theorem 8.2. *Suppose there is a Hadamard matrix of order n . Then there exists a $\{0, n/4\}$ -code of size $2(n^2 - 1)$ in $\mathcal{G}_{n/2,n}$.*

When the dimension of the complex space is an odd prime power, there is another construction which achieves the relative bound with equality. The following is the complex version of a set of real Grassmannian packings due to Calderbank, Hardin, Rains, Shor, and Sloane [7]. For lack of another reference in the complex case, the details are included here.

Let $V := \mathbb{F}_q^n$, where $q = p^k$ and p is an odd prime, and let $\{e_v : v \in V\}$ be the standard basis for $\mathbb{C}^{q^n}$. Then define the $q^n \times q^n$ Pauli matrices

$$\begin{aligned} X(a) : e_v &\mapsto e_{v+a}, \\ Y(a) : e_v &\mapsto \omega^{\text{tr}(a^T v)} e_v, \end{aligned}$$

where ω is a p -th primitive root of unity. Note that e_v is an eigenvalue for $Y(a)$ and $e_v^* := \sum_a \omega^{\text{tr}(a^T v)} e_a$ is an eigenvalue for $X(a)$. Define the *extraspecial Pauli group* E to be generated by all $X(a), Y(a)$, and ωI ; it has pq^n elements,

all of the form $\omega^i X(a)Y(b)$, for $i \in \mathbb{Z}_p$, $a, b \in V$. Its center is $Z(E) = \langle \omega I \rangle$, and $\overline{E} := E/Z(E)$ is Abelian and therefore a vector space isomorphic to V^2 under the mapping

$$(a, b) \mapsto X(a)Y(b)/Z(E).$$

The space V^2 has a nondegenerate alternating bilinear form (a *symplectic* form), namely

$$\langle (a_1, b_1), (a_2, b_2) \rangle := \text{tr}(a_1^T b_2 - a_2^T b_1).$$

It is not difficult to check that two elements in E , say $w^i X(a_1)Y(b_1)$ and $w^j X(a_2)Y(b_2)$, commute if and only if their images in $E/Z(E)$ satisfy

$$\langle (a_1, b_1), (a_2, b_2) \rangle = 0.$$

Subspaces on which the symplectic form vanishes are called *totally isotropic*. Therefore, a subspace $\overline{W}$ of $E/Z(E)$ is totally isotropic if and only if its preimage W in E is an Abelian subgroup.

We now use characters of subgroups of E to define elements of $\mathcal{G}_{q^k, q^n}$. Let $\overline{W}$ be a totally isotropic subspace of $E/Z(E)$ of dimension $n - k$, and let W be the preimage of $\overline{W}$ in E . If $\chi : \overline{W} \rightarrow \mathbb{C}$ is a character of $\overline{W}$, then $\chi' : W \rightarrow \mathbb{C}$ defined by

$$\chi'(\omega^i X(a)Y(b)) = \omega^{-i} \chi(X(a)Y(b)/Z(E))$$

is a character of W . Define a matrix

$$\Pi_\chi := \frac{1}{|W|} \sum_{g \in W} \chi'(g)g.$$

Lemma 8.3. *If $\overline{W}$ is an $(n - k)$ -dimensional totally isotropic subspace of $E/Z(E)$ and χ is a character of $\overline{W}$, then Π_χ is the projection matrix for a q^k -dimensional subspace of $\mathbb{C}^{q^n}$ which is invariant under the action of W .*

Proof. It is not difficult to check that Π_χ is Hermitian and $\Pi_\chi^2 = \Pi_\chi$. It is also not difficult to check that $\Pi_\chi v$ is an eigenvector of $g \in W$ for any $v \in \mathbb{C}^{q^n}$, so Π_χ is a projection matrix for an invariant subspace. The rank of Π_χ is the trace of Π_χ , which can be computed as follows, after noting that the only elements of E with non-zero trace are the multiples of the identity:

$$\text{tr}(\Pi_\chi) = \frac{1}{|W|} \sum_{g = \omega^i I} \chi'(g) \text{tr}(g) = \frac{1}{pq^{n-k}} \sum_{i=1}^p \omega^{-i} \text{tr}(\omega^i I) = q^k. \quad \square$$

In the construction that follows we require the q -binomial coefficients, defined as

$$\begin{bmatrix} n \\ m \end{bmatrix}_q := \frac{(q^n - 1) \dots (q^{n-m+1} - 1)}{(q^m - 1) \dots (q - 1)}.$$

Theorem 8.4. For $0 \leq k \leq n-1$, let S be the set of all q^k -dimensional invariant subspaces of the preimages W of all $(n-k)$ -dimensional totally isotropic subspaces $\overline{W}$ of $E/Z(E)$ (as described in Lemma 8.3). Then S is a $(n-k+1)$ -distance set in $\mathcal{G}_{q^k, q^n}$ of size

$$q^{n-k} \begin{bmatrix} n \\ n-k \end{bmatrix}_q \prod_{i=k+1}^n (q^i + 1).$$

Proof. For $j \in \{1, 2\}$, let $\overline{W}_j$ be an isotropic subspace of $E/Z(E)$, let W_j be its Abelian preimage in E , let χ_j be a character of $\overline{W}_j$, and let $\Pi_j := \Pi_{\chi_j}$ as in Lemma 8.3. Then

$$\begin{aligned} \text{tr}(\Pi_1 \Pi_2) &= \frac{1}{|\overline{W}_1| |\overline{W}_2|} \sum_{g_1 \in W_1} \sum_{g_2 \in S_2} \chi'_1(g_1) \chi'_2(g_2) \text{tr}(g_1 g_2) \\ &= \frac{1}{|\overline{W}_1| |\overline{W}_2|} \sum_{g_1 \in W_1 \cap W_2} \sum_{g_2 = \omega^i g_1^{-1}} \chi'_1(g_1) \chi'_2(g_2) \text{tr}(\omega^i I) \\ &= \frac{pq^n |W_1 \cap W_2|}{|\overline{W}_1| |\overline{W}_2|} \text{ (or 0, depending on } \chi'_1 \text{ and } \chi'_2) \\ &= \frac{q^n |\overline{W}_1 \cap \overline{W}_2|}{|\overline{W}_1| |\overline{W}_2|} \text{ (or 0).} \end{aligned}$$

Furthermore, any two distinct invariant subspaces from the same isotropic $\overline{W}_j$ are orthogonal. If $\overline{W}_1 \neq \overline{W}_2$, then $\dim(\overline{W}_1 \cap \overline{W}_2) \in \{0, 1, \dots, n-k-1\}$ and so $|\overline{W}_1 \cap \overline{W}_2|$ takes $n-k$ possible values. It follows that S is a $(n-k+1)$ -distance set. To find the size of S , first note that the number of isotropic subspaces of dimension $n-k$ is (see [5, Lemma 9.4.1])

$$\begin{bmatrix} n \\ n-k \end{bmatrix}_q \prod_{i=k+1}^n (q^i + 1)$$

and then note that each isotropic subspace produces q^{n-k} invariant subspaces. $\square$

In the case $k = n-1$, Theorem 8.4 produces a 2-distance set in $\mathcal{G}_{q^{n-1}, q^n}$ of size $\frac{q(q^{2n}-1)}{q-1}$. The inner product values that occur are $\alpha = 0$ and $\beta = q^{n-2}$: this construction achieves equality in the relative bound (Corollary 6.6). In his thesis, Zauner [25] has a construction which has these same parameters (in fact, Zauner's construction is more general, as it also allows q to be an even

prime power). In the case $k = n - 2$, we get a 3-distance set in $\mathcal{G}_{q^{n-2}, q^n}$ of size $\frac{q^2(q^{2n}-1)(q^{2n-2}-1)}{(q^2-1)(q-1)}$, with inner product values $\alpha = 0$, $\beta = q^{n-4}$, and $\gamma = q^{n-3}$.

There are many open questions regarding whether or not tightness in the bounds can be achieved; in particular, it is not known if there are any examples of subspaces achieving equality in the absolute bound (Corollary 6.2) for $m > 1$. The smallest nontrivial case is a set of 16 subspaces of dimension 2 in $\mathbb{C}^4$, with an inner product value of $\alpha = 14/15$.

9 Designs

In this section, we introduce the concept of a *complex Grassmannian 2-design*. We give lower bounds for the size of a t -design and indicate the relationship between designs and codes.

Recall that $H_t(m, n)$ is the direct sum of the irreducible representations H_μ of $U(n)$ containing the zonal polynomials $Z_{\mu, a}$, where μ is an integer partition of size at most t and length at most m . $H_t(m, n)$ may also be thought of as the symmetric polynomials of degree at most t in the principle angles of pairs of subspaces in $\mathcal{G}_{m, n}$. Since the zonal orthogonal polynomials $Z_{\mu, a}$ (with $|\mu| \leq t$ and $\text{len}(\mu) \leq m$) span $H_t(m, n)$ and are contained in $\text{Hom}_t(n)$, it follows that $H_t(m, n)$ is a subspace of $\text{Hom}_t(n)$.

We call a finite subset $S \subseteq \mathcal{G}_{m, n}$ a t -design if, for every polynomial f in $H_t(m, n)$,

$$\frac{1}{|S|} \sum_{a \in S} f(a) = \int_{\mathcal{G}_{m, n}} f(c) \, dc.$$

In other words, the average of f over S is the same as the average of f over the entire Grassmannian space. Recall that the average of f over $\mathcal{G}_{m, n}$ can be written as $\langle 1, f \rangle$: with this in mind we define an inner product for functions on S as follows:

$$\langle f, g \rangle_S := \frac{1}{|S|} \sum_{a \in S} \overline{f(a)} g(a).$$

Then S is a t -design if $\langle 1, f \rangle = \langle 1, f \rangle_S$ for every $f \in H_t(m, n)$. Equivalently, the zonal orthogonal polynomials $Z_{\mu, a}$ span H_μ , so S is a t -design if every $Z_{\mu, a}$ has the same averages over S and $\mathcal{G}_{m, n}$, where μ is a partition of at most t into at most m parts.

By way of example, consider Theorem 6.4. If $f = \sum_{\mu} c_{\mu} g_{\mu}$ and $c_{\mu} > 0$ for every $|\mu| \leq t$, then equality in Theorem 6.4 implies that S is a t -design.

For the purposes of quantum tomography applications, 1- and 2-designs play a special role (see [13], as well as [21]). In those cases, there is a more explicit description of a t -design.

Lemma 9.1. *Let S be a finite subset of $\mathcal{G}_{m,n}$. Then S is a 1-design if and only if*

$$\frac{1}{|S|} \sum_{a \in S} P_a = \int_{\mathcal{G}_{m,n}} P_a da = \frac{m}{n} I.$$

Moreover, S is a 2-design if and only if

$$\frac{1}{|S|} \sum_{a \in S} P_a \otimes P_a = \int_{\mathcal{G}_{m,n}} P_a \otimes P_a da. \quad (9.1)$$

Before proving Lemma 9.1, we note the integral on the RHS of equation (9.1) can be evaluated explicitly. Writing $P_a = \sum_{i=1}^m a_i a_i^*$ for some orthonormal basis $\{a_i\}$ of a , and letting T denote the “swap” operator $T : e_i \otimes e_j \mapsto e_j \otimes e_i$, the integral is obtained from Lemma 5.3 of [20]:

$$\int_{\mathcal{G}_{m,n}} P_a \otimes P_a da = \frac{m}{n(n^2 - 1)} [(nm - 1)I + (n - m)T].$$

Proof. We prove the lemma by showing that $H_t = \text{Hom}_t$ for $t \in \{1, 2\}$; the result then follows by considering the polynomials of the form $a \mapsto (P_a)_{ij}$ in Hom_1 and $a \mapsto (P_a)_{ij}(P_a)_{kl}$ in Hom_2 .

Recall that H_t is contained in Hom_t , so it suffices to show that the dimensions of the spaces are equal. When $t = 1$, we have $\dim(H_1) = \dim(\text{Hom}_1) = n^2$, so $H_1 = \text{Hom}_1$. When $t = 2$, recall that $\dim(H_2) = \binom{n^2}{2}$ (assuming $m > 1$), and the space of homogeneous degree-2 polynomials on the coordinates of $n \times n$ matrices has dimension $\binom{n^2+1}{2}$. However, Hom_2 is the space of degree-2 polynomials on projection matrices, not general matrices. If P_a is a projection matrix, then the degree-2 polynomial

$$P_a \mapsto m \text{tr}(AP_a^2) - \text{tr}(P_a) \text{tr}(AP_a)$$

is identically zero for every A . There are n^2 linearly independent polynomials of that form for general $n \times n$ matrices; therefore,

$$\dim(\text{Hom}_2) = \binom{n^2 + 1}{2} - n^2 = \binom{n^2}{2}.$$

Thus $H_2 = \text{Hom}_2$. □

We now consider bounds for t -designs. The following is the *absolute bound*.

Lemma 9.2. *If S is a t -design, then*

$$|S| \geq \dim(H_{\lfloor t/2 \rfloor}(m, n)).$$

Proof. Let $\{e_1, \dots, e_N\}$ be an orthonormal basis for $H_{\lfloor t/2 \rfloor}$. Since e_i is a symmetric polynomial in the eigenvalues, so is $\overline{e_i}e_j$. It follows from the unique decomposition of $L^2(\mathcal{G}_{m,n})$ that $\overline{e_i}e_j$ is in $H_{2\lfloor t/2 \rfloor}$ and therefore in H_t . If S is a t -design, and $\overline{e_i}e_j$ is in H_t , then

$$\langle e_i, e_j \rangle = \langle 1, \overline{e_i}e_j \rangle = \langle 1, \overline{e_i}e_j \rangle_S = \langle e_i, e_j \rangle_S,$$

whence it follows that $\{e_1, \dots, e_l\}$ are orthogonal as functions of S (a space of dimension $|S|$). $\square$

If equality holds, then the basis for $H_{t/2}(m, n)$ is also a basis for the functions on S . There is also a *relative bound*.

Theorem 9.3. *Let $f(x_1, \dots, x_m) \in \mathbb{R}[x]$ be a symmetric polynomial such that $f = \sum_{\mu} c_{\mu} Z_{\mu}$, where Z_{μ} is a zonal polynomial for the Grassmanian space, and $c_0 > 0$. Furthermore, suppose S is a t -design such that $f_a(b) = f(y_1(a, b), \dots, y_m(a, b)) \geq 0$ for every $a \neq b$ in S , and $c_{\mu} \leq 0$ for every $|\mu| > t$. Then*

$$|S| \geq \frac{f(1, \dots, 1)}{c_0}.$$

Proof. Let f_a be the zonal polynomial of f at a , so that $f_a(b) \geq 0$ for $b \neq a$. Summing over all $b \in S$,

$$|S| \langle 1, f_a \rangle_S \geq f_a(a) = f(1, \dots, 1).$$

Again averaging over all $a \in S$,

$$\begin{aligned} f(1, \dots, 1) &\leq \sum_{a \in S} \langle 1, f_a \rangle_S \\ &= \sum_{a \in S} \sum_{\mu} c_{\mu} \langle 1, Z_{\mu, a} \rangle_S \\ &= \sum_{\mu} c_{\mu} \sum_{a \in S} \langle 1, Z_{\mu, a} \rangle_S. \end{aligned}$$

Since S is a t -design, the inner sum is zero for $|\mu| \leq t$ ($\mu \neq 0$). For $|\mu| > t$, the inner sum is nonnegative (by Lemma 5.1) and $c_\mu \leq 0$. Therefore,

$$\begin{aligned} f(1) &\leq c_0 \sum_{a \in S} \langle 1, Z_{0,a} \rangle_S \\ &= c_0 |S|. \end{aligned} \quad \square$$

If equality holds, then we have $f(a, b) = 0$ for every $a \neq b$ in S . That is, S is an f -code. Furthermore, for every $|\mu| > t$, we have either $c_\mu = 0$ or $\sum_{a \in S} Z_{\mu,a} = 0$.

As with classical codes and designs, the case where S is both a f -code and a t -design is of particular interest, as the size of the set can be determined exactly. Combining Theorems 6.4 and 9.3 gives the following.

Theorem 9.4. *Suppose S is an f -code for $f = \sum_\mu c_\mu Z_\mu$, where $c_\mu \geq 0$, and S is also a t -design for $t \geq \deg(f)$. Then*

$$|S| = \frac{f(1, 1, \dots, 1)}{c_0}.$$

Consider the following polynomial in $H_t(m, n)$:

$$Z_t := \sum_{\substack{|\mu| \leq t \\ \text{len}(\mu) \leq m}} Z_\mu.$$

This polynomial satisfies $\langle Z_{t,a}, f \rangle = f(a)$ for every $f \in H_t(m, n)$. Taking $f = Z_t$ in Theorem 9.4, we get:

Corollary 9.5. *If S is a Z_t -code and a $2t$ -design, then*

$$|S| = \dim(H_t(m, n)).$$

Theorem 9.6. *Any two of the following imply the third:*

- S is an f -code, where $\deg(f) = t$;
- S is a $2t$ -design;
- $|S| = \dim(H_t(m, n))$.

Proof. Suppose S is a f -code with $|S| = \dim(H_t)$. Since equality holds in Corollary 6.3, the polynomials f_a are a basis for H_t . However, we have

$$\langle Z_{t,a}, f_b \rangle = f_b(a) = \begin{cases} 0, & b \neq a; \\ f(1, 1, \dots, 1), & b = a. \end{cases}$$

Thus $\{Z_{t,a}\}$ is a dual basis for H_t and each $Z_{t,a}$ is a multiple of $f_{t,a}$. Now consider the averages $\langle Z_{t,a}, f_b \rangle_S$: since $f_a(b) = Z_{t,a}(b) = 0$ for $b \neq a$, we get

$$\langle Z_{t,a}, f_b \rangle_S = \begin{cases} 0, & b \neq a; \\ f(1, 1, \dots, 1), & b = a. \end{cases}$$

Thus we have

$$\langle 1, Z_{t,a} f_b \rangle_S = \langle \overline{Z_{t,a}}, f_b \rangle_S = \langle \overline{Z_{t,a}}, f_b \rangle = \langle 1, Z_{t,a} f_b \rangle$$

for the bases $\{Z_{t,a}\}$ and $\{f_b\}$. But the set $\{Z_{t,a} f_b\}$ spans $H_{2t}(n)$, so S is a $2t$ -design.

Conversely, suppose S is a $2t$ -design with $|S| = \dim(H_t)$, and let f annihilate of the angle set of A . Since H_t spans the functions on $|S|$, each f_a is in H_t and is therefore a polynomial of degree t . Thus f has degree t . $\square$

The simplest case of Theorem 9.6 is when $t = 1$: in this case, S is a 1-distance set and a 2-design of size n^2 . Moreover, S is a Z_1 -code, and Z_1 is the annihilator of $\frac{m(mn-1)}{n^2-1}$. Thus the inner product between every two distinct subspaces is $\alpha = \frac{m(mn-1)}{n^2-1}$.

10 Association schemes

As Theorem 9.6 indicates, sets of Grassmannian subspaces which reach equality in the Delsarte bounds have a great deal of structure. In this section, we show that—much like spherical codes and spherical designs—these sets are often endowed with the structure of an association scheme.

Let S be an f -code with a finite number of distinct sets of principal angles $y = (y_1, \dots, y_m)$. Denote the set of y 's that occur by $\mathcal{Y}$. For each $y \in \mathcal{Y}$, define a $|S| \times |S|$ matrix as follows:

$$A_y(a, b) := \begin{cases} 1, & a, b \text{ have principal angles } y; \\ 0, & \text{otherwise.} \end{cases}$$

Each A_y is a symmetric $\{0, 1\}$ -matrix. Furthermore, each pair (a, b) has some principal angle y , so $\sum_{y \in \mathcal{Y}} A_y = J$, where J is the all-ones matrix. If $y_0 := (1, \dots, 1)$ denotes the trivial principal angles set, then $A_0 := A_{y_0}$ is the identity matrix. We will call the A_y matrices *Schur idempotents*, as they are idempotent under Schur multiplication, defined as follows:

$$(A \circ B)_{ij} := A_{ij} B_{ij}.$$

Under certain conditions, these Schur idempotents form an association scheme.

For each integer partition μ and corresponding zonal polynomial Z_μ , define an $|S| \times |S|$ matrix as follows:

$$E_\mu(a, b) := \frac{1}{|S|} Z_\mu(a, b).$$

Each E_μ is also symmetric and in the span of $\{A_y\}_{y \in \mathcal{Y}}$:

$$E_\mu = \frac{1}{|S|} \sum_{y \in \mathcal{Y}} Z_\mu(y) A_y.$$

In particular, E_0 is a scalar multiple of J . When $\{A_y\}_{y \in \mathcal{Y}}$ forms an association scheme, the matrices E_μ are the scheme's idempotents.

Lemma 10.1. *If S is a $2t$ -design, then $\{E_\mu\}_{|\mu| \leq t, \text{len}(\mu) \leq m}$ are a set of orthogonal idempotents.*

Proof. Suppose $|\mu| = i$ and $|\lambda| = j$, with $i, j \leq t$. Then

$$\begin{aligned} (E_\mu E_\lambda)_{a,b} &= \frac{1}{|S|^2} \sum_{c \in S} Z_\mu(a, c) Z_\lambda(c, b) \\ &= \frac{1}{|S|} \langle Z_{\mu,a}, Z_{\lambda,b} \rangle_S. \end{aligned}$$

Since $Z_{\mu,a}$ and $Z_{\mu,b}$ are in H_t , their product is in H_{2t} . Now S is a $2t$ -design, so the average of $Z_{\mu,a} Z_{\lambda,b}$ over S is the same as the average over $\mathcal{G}_{m,n}$. But

$$\langle Z_{\mu,a}, Z_{\lambda,b} \rangle = \delta_{\lambda,\mu} Z_\mu(a, b),$$

and so we find that $E_\mu E_\lambda = \delta_{\lambda,\mu} E_\mu$. $\square$

More generally, if $|\mu| = i$ and $|\lambda| = j$, and S is a $(i+j)$ -design, then E_μ and E_λ are orthogonal.

Now suppose S is a $2t$ -design. By the previous lemma $\{E_\mu\}_{|\mu| \leq t}$ are linearly independent, and clearly the matrices $\{A_y\}_{y \in \mathcal{Y}}$ are also linearly independent. If $|\mathcal{Y}|$ equals the number of partitions of at most t (into at most m parts), then the span of $\{A_y\}_{y \in \mathcal{Y}}$ and $\{E_\mu\}_{|\mu| \leq t}$ are the same. Since $\{E_\mu\}_{|\mu| \leq t}$ is closed under multiplication, so too is the span of $\{A_y\}_{y \in \mathcal{Y}}$, and so we have an association scheme.

Corollary 10.2. *Let S be a $2t$ -design in $\mathcal{G}_{m,n}$ with principal angle set $\mathcal{Y}$. If $|\mathcal{Y}|$ is equal to the total number of partitions of $0, 1, \dots, t$ into at most m parts, then $\{A_y\}_{y \in \mathcal{Y}}$ is an association scheme.*

Lemma 10.3. *Let S be a $2t$ -design in $\mathcal{G}_{m,n}$ with principal angle set $\mathcal{Y}$ such that $|\mathcal{Y}|$ is the total number of partitions of $0, 1, \dots, t$ into at most m parts. Then $\{E_\mu\}_{|\mu| \leq t, \text{len}(\mu) \leq m}$ are the idempotents of the scheme $\{A_y\}_{y \in \mathcal{Y}}$.*

Proof. Since $E_\mu = \frac{1}{|S|} \sum_{y \in \mathcal{Y}} Z_\mu(y) A_y$, we see that the matrix $[Z_\mu(y)]$ is the transition matrix between the two bases of the association scheme and is therefore invertible. It follows that for each y_i in $\mathcal{Y}$, some linear combination of the rows Z_μ forms a homogeneous degree- t polynomial g_i such that $g_i(y_j) = \delta_{ij}$. (Conversely, if such g_i polynomials exist, then $[Z_\mu(y)]$ is invertible.) Then

$$\begin{aligned} (A_i E_\mu)_{a,b} &= \frac{1}{|S|} \sum_{c: y(a,c)=y_i} Z_\mu(c,b) \\ &= \langle g_{i,a}, Z_{\mu,b} \rangle_S \\ &= \langle g_{i,a}, Z_{\mu,b} \rangle. \end{aligned}$$

Now write $g_i = \sum_{|\lambda| \leq t} c_{i,\lambda} Z_\lambda$, so that

$$\langle g_{i,a}, Z_{\mu,b} \rangle = \sum_{|\lambda| \leq t} c_{i,\lambda} \langle Z_{\lambda,a}, Z_{\mu,b} \rangle = c_{i,\mu} Z_\mu(a,b).$$

Thus $A_i E_\mu = c_{i,\mu} E_\mu$ for some $c_{i,\mu}$. □

By way of example, let $t = 1$, and suppose S is a 2-design with only one nontrivial principal angle set (and one trivial one, for a total of two). The number of partitions of at most 1 is also two ($\mu = 0$ and $\mu = (1)$), so by Corollary 10.2 we have an association scheme. In this case the scheme is the trivial one, namely $\{I, J - I\}$.

As another example of an association scheme obtained from principal angles, consider the collection of subspaces in $\mathcal{G}_{n/2,n}$ from Theorem 8.1. This collection has four distinct sets of principal angles:

$$\begin{aligned} y &= (1, \dots, 1) \quad (\text{trivial principal angles}), \\ y &= (0, \dots, 0) \quad (\text{angles between } a \text{ and } a^\perp), \\ y &= (\underbrace{1, \dots, 1}_{n/4}, \underbrace{0, \dots, 0}_{n/4}), \\ y &= (\tfrac{1}{2}, \dots, \tfrac{1}{2}). \end{aligned}$$

While $|\mathcal{Y}| = 4$ is the number of partitions of at most 2 ($\mu = 0$, $\mu = (1)$, $\mu = (1, 1)$ and $\mu = (2)$), the hypotheses of Corollary 10.2 are not satisfied

because the subspaces do not form a 4-design. Nevertheless, it is easy to verify computationally that this collection does give a 3-class association scheme.

We may define a coarser set of relations on an f -code S using the sums of principal angles—the inner products of the projection matrices—instead of the principal angles themselves. Let $\mathcal{A}$ denote the set of nontrivial inner product values that occur in S , so S is an $\mathcal{A}$ -code. For $\alpha \in \mathcal{A}$ let A'_α be the $|S| \times |S|$ matrix defined as follows:

$$A'_\alpha(a, b) := \begin{cases} 1, & \text{tr}(P_a P_b) = \alpha, \\ 0, & \text{otherwise.} \end{cases}$$

Also define $A'_m := I$ for the identity relation. Clearly each A'_α is in the span of $\{A_y : y \in \mathcal{Y}\}$; in fact

$$A'_\alpha = \sum_{y \in \mathcal{Y}: \sum y_i = \alpha} A_y.$$

In particular, $A'_m = A_0 = I$, and if 0 is in $\mathcal{A}$, then $A'_0 = A_{(0, \dots, 0)}$. As before, the matrices are Schur idempotents and sum to J . Next we need the corresponding idempotents. For each $i \in \{0, \dots, t\}$, define E'_i as follows:

$$E'_i := \sum_{|\mu|=i} E_\mu.$$

This implies that $E'_0 = J/|S|$ and $E'_i(a, b) = (Z_i(a, b) - Z_{i-1}(a, b))/|S|$ for $i > 0$. As in Lemma 10.1, if S is a $2t$ -design, then $\{E'_i : i \leq t\}$ is a set of orthogonal idempotents, and if S is a $(2t - 1)$ -design, then $\{E'_i : i \leq t\}$ are linearly independent.

Clearly E'_i is in the span of $\{A_y : y \in \mathcal{Y}\}$, since each E_μ is in that span. But suppose $Z_i(y)$ is the annihilator polynomial of some i -distance set, so it is a only function of $\sum_i y_i$: then in fact E'_i is in the span of $\{A'_\alpha : \alpha \in \mathcal{A}\}$. If $Z_i(y)$ is an annihilator for sufficiently many i , then $\{E'_i : 0 \leq i \leq t\}$ and $\{A'_\alpha : \alpha \in \mathcal{A} \cup \{m\}\}$ span the same set, and that set is closed under multiplication.

Corollary 10.4. *Let S be a $2t$ -design that is also an $\mathcal{A}$ -code in $\mathcal{G}_{m,n}$. If $|\mathcal{A}| \leq t$, and $Z_i(y)$ is an annihilator polynomial for each $i \leq t$, then $\{A'_\alpha : \alpha \in \mathcal{A} \cup \{m\}\}$ is an association scheme.*

In fact, these hypotheses can be weakened.

Theorem 10.5. *Let S be a $(2t - 2)$ -design that is also an $\mathcal{A}$ -code in $\mathcal{G}_{m,n}$. If $|\mathcal{A}| = t$, and $Z_i(y)$ is an annihilator for each $0 \leq i \leq t - 1$, then $\{A'_\alpha : \alpha \in \mathcal{A} \cup \{m\}\}$ is an association scheme.*

Proof. Since S is a $2(t-1)$ -design, the idempotents $\{E'_i : 0 \leq i \leq t-1\}$ are linearly independent. We claim that I is also linearly independent from $\{E'_i : 0 \leq i \leq t-1\}$. For, if $I = \sum_{i=0}^{t-1} c_i E'_i$, then the off-diagonal entries of I are functions of a polynomial of degree at most $t-1$ in $\sum_j y_j$, namely

$$\frac{1}{|S|} \left(c_0 + \sum_{i=1}^{t-1} c_i (Z_i(y) - Z_{i-1}(y)) \right).$$

But all off-diagonal entries are 0, implying that the polynomial has t roots in $\sum_i y_i$, a contradiction. So $\{E'_i : 0 \leq i \leq t-1\} \cup \{I\}$ is linearly independent and therefore spans $\{A'_\alpha : \alpha \in \mathcal{A} \cup \{m\}\}$. Since it is closed under multiplication, we have an association scheme. $\square$

By way of example, suppose $t = 2$ in Theorem 10.5. Note that $Z_0(y)$ and $Z_1(y)$ are always annihilators. It follows that if S is a 2-design, and the inner product set $\mathcal{A} = \{\text{tr}(P_a P_b) : a \neq b \in S\}$ contains exactly two distinct values, then $\{A'_\alpha : \alpha \in \mathcal{A} \cup \{m\}\}$ is a 2-class association scheme.

Corollary 10.6. *Let S be a $(2t-2)$ -design and an $\mathcal{A}$ -code in $\mathcal{G}_{m,n}$ such that $|\mathcal{A}| = t$ and $Z_i(y)$ is an annihilator for $i \leq t-1$. Then the idempotents of the scheme $\{A'_\alpha : \alpha \in \mathcal{A} \cup \{m\}\}$ are $E'_0, \dots, E'_{t-1}$, and $J - \sum_{i=0}^{t-1} E'_i$.*

Proof. Let f_α denote the annihilator polynomial of $\mathcal{A} \setminus \{\alpha_0, \alpha\}$, normalized so that $f_\alpha(\alpha) = 1$. Then f_α is a polynomial of degree $t-1$ in $\sum_i y_i$, and the corresponding zonal polynomial $f_{\alpha,a}$ is in $H_{t-1}(n)$. Writing $P_i := Z_i - Z_{i-1} = \sum_{|\mu|=i} Z_\mu$, we have

$$\begin{aligned} (A'_\alpha E'_i)_{a,b} &= \frac{1}{|S|} \sum_{\text{tr}(P_a P_c) = \alpha} P_i(\text{tr}(P_c P_b)) \\ &= \langle f_{\alpha,a}, P_{i,b} \rangle_S - \frac{f_\alpha(m)}{|S|} P_i(\text{tr}(P_a P_b)) \\ &= \langle f_{\alpha,a}, P_{i,b} \rangle - \frac{f_\alpha(m)}{|S|} P_i(\text{tr}(P_a P_b)). \end{aligned}$$

Now decomposing into its degrees as $f_\alpha = \sum_i c_{\alpha,i} P_i$, we get

$$\begin{aligned} (A'_\alpha E'_i)_{a,b} &= c_{\alpha,i} \langle P_{i,a}, P_{i,b} \rangle - \frac{f_\alpha(m)}{|S|} P_i(\text{tr}(P_a P_b)) \\ &= c_{\alpha,i} P_i(\text{tr}(P_a P_b)) - \frac{f_\alpha(m)}{|S|} P_i(\text{tr}(P_a P_b)) \\ &= (c_{\alpha,i} |S| - f_\alpha(m)) (E'_i)_{a,b}. \end{aligned}$$

Thus $A'_\alpha E'_i = \lambda_{\alpha,i} E'_i$ for some constant $\lambda_{\alpha,i}$. $\square$
